

Impact on Power System Stability

Dr.-Ing. Markus Pöller

Power System Stability

- „Stability“ - general definition:
Ability of a system to return to a steady state after a disturbance.
- Small signal effects
- Large signal effects (nonlinear dynamics)

- **Power System Stability - definition according to CIGRE/IEEE:**
- Rotor angle stability (oscillatory, transient-stability)
- Voltage stability (short-term, long-term, dynamic)
- Frequency stability

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power System Stability – Global vs. local stability

Local effects:

- Loss of synchronism of an individual generator.
- „Run-away“ condition of induction generators.
- Trip of wind generators due to voltage sags.

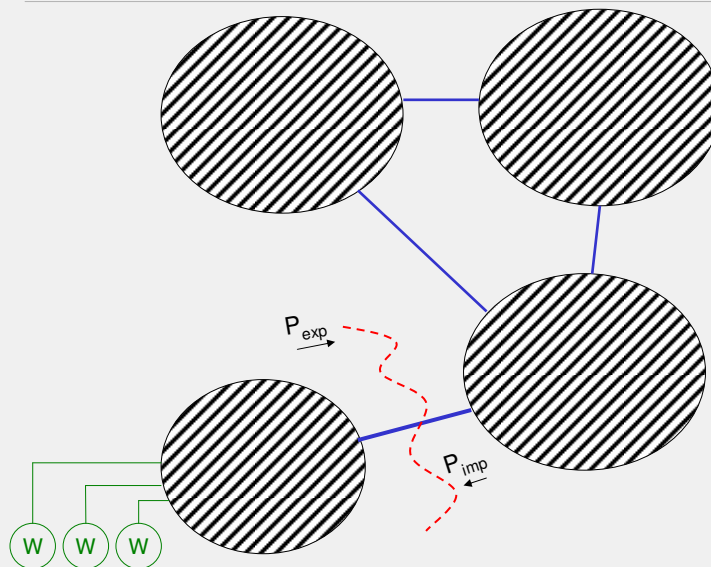

Global effects:

- Loss of synchronism between network areas -> islanding
- Inter-area oscillations with insufficient damping
- Frequency drop -> excessive load shedding
- Voltage collapse -> system blackout

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Wind Generator Impact on Inter-Regional Transfer Limits

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Limitation of Inter-Regional Power Transfers

Power Export:

- Thermal Limits of Tie-Lines
- Transient Stability
- Oscillatory Stability (Damping)

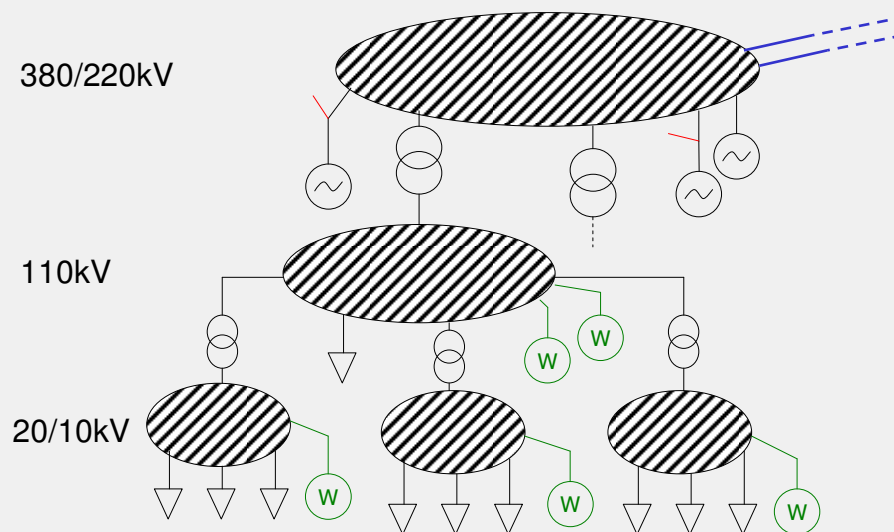

Power Import:

- Thermal Limits of Tie-Lines
- Voltage Stability (especially Generator Outage)
- Frequency Stability (Islanding)

Power Systems with High Level of Wind Generation

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Export

The diagram shows three circular nodes, each filled with diagonal hatching, connected by blue lines. The nodes are arranged in a triangle with a fourth node below the center. A red dashed arrow labeled P_{exp} points from the bottom-right node towards the right, indicating power export.

DlgSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Export – Transient Stability

What is different with wind generation?

- Different generator technology.
- Connection to lower voltage levels.
- Larger average distances between synchronous generation.

Influence on Export-Limit?

DlgSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Export – Transient Stability

Simulation, Pexp=90MW

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Export – Transient Stability

Simulation, Pexp=180MW

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Transient Stability and Wind Power – Basic Considerations

- Wind generator modelling as „static generator“, assuming:
 - P-control
 - Q-control

- Aggrupration of all wind generators in one region

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Export – Transient Stability

$$P_G = P_L - P_W + P_{\text{exp}} = P_L - P_W + \frac{U_1 U_2}{X} \sin \delta_{12}$$

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

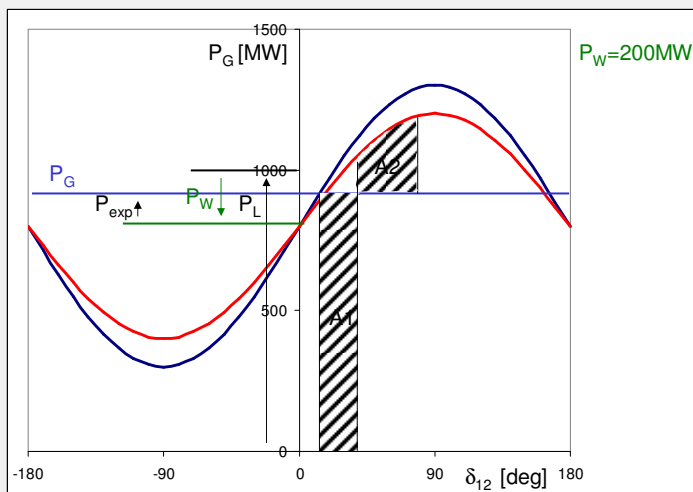

Power Export – Transient Stability

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Export – Transient Stability

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Export – Transient Stability

„Static“ generator technology increases transient stability limits:

- Kinetic energy is reduced because less synchronous generators are connected to the grid.
- Rotor angle deviation during fault remains almost constant because acceleration time constant referred to total synchronous generation has not changed.
- Result: area A1 small, „room“ für A2 remains unchanged -> Increase of transient stability limits.

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

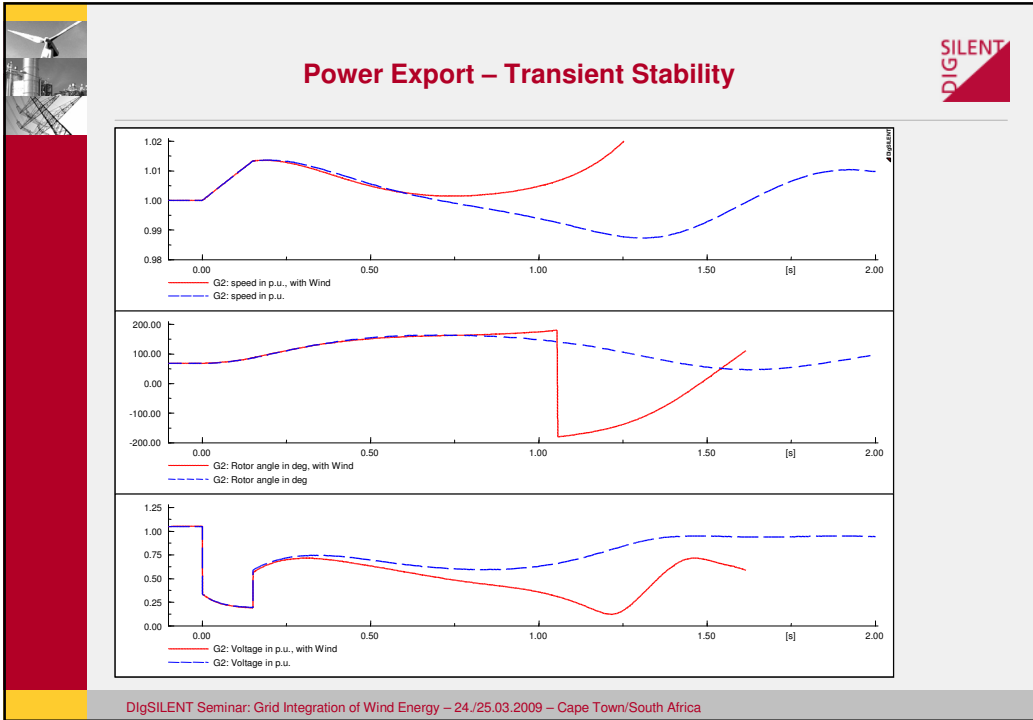

Limits of Inter-Regional Power Flows

Case 2

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

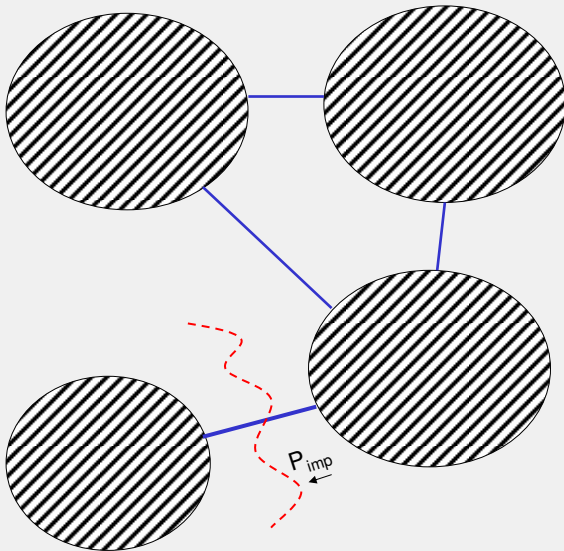

- ### Power Export – Transient Stability
- Positive:
- Lower level of kinetic energy increase during fault.
 - > Increase of transient stability export limits.
 - > Improved voltage recovery.
- Negative:
- Larger voltage dip during fault.
 - Dynamic reactive power reserve reduced because of missing voltage control capability and connection to subtransmission areas.
 - Increase of average distance between synchronous generation, higher transfer impedances.
- DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Import – Voltage Stability

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Long-Term vs. Short-Term Voltage Stability

Reactive power control:

	Short-Term	Long-Term
Q- contribution of synchronous gen.	Large (thermal overload capabilities)	Limited by overexcitation limitors
Switchable shunts	No contribution (switching times too high)	High contribution
SVC/TSC	High contribution	High contribution

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

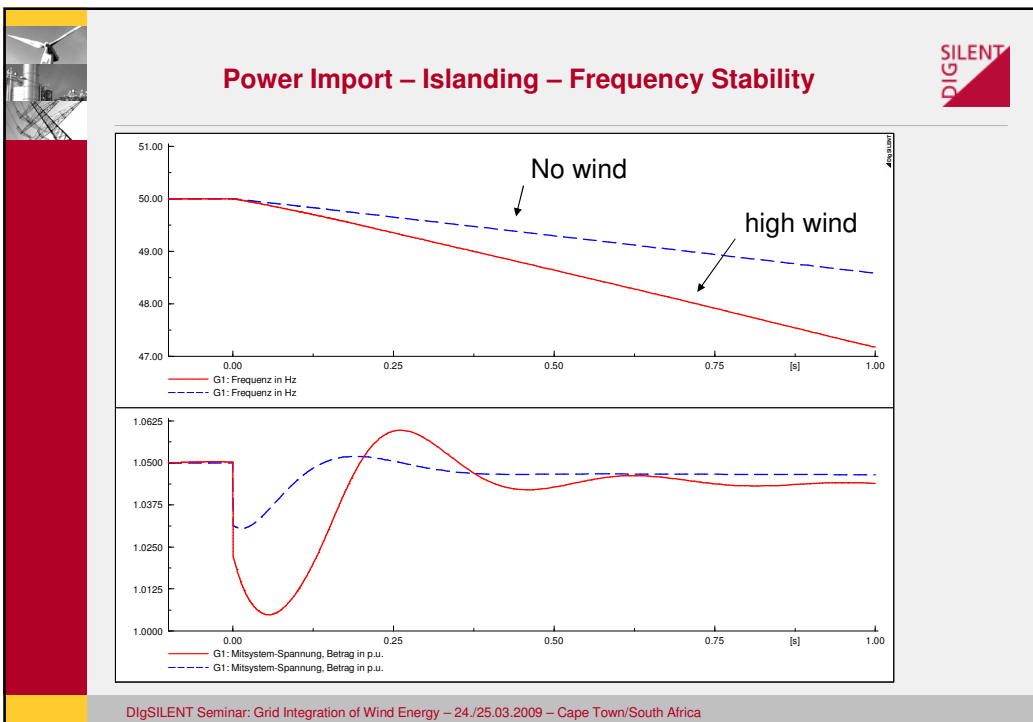

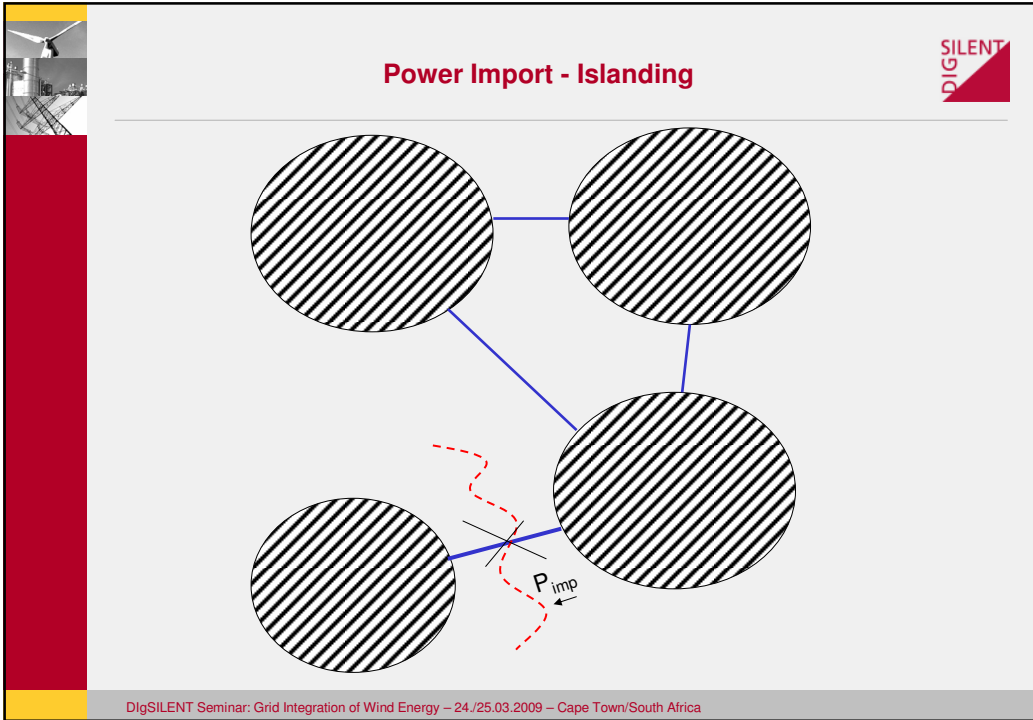

Power Import – Generator Outage – Wind Generator Impact

SILENT
DIG

Wind generator impact on voltage stability:

- Basically no influence of „static generation“ on voltage stability limits.
- Reduced reactive power reserves shifts the system closer to voltage stability limits.
- Unreliable active power output of wind mills amplifies generator outage problem (cascading outages).

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Power Import – Islanding

Islanding results in frequency stability problems ($P_{imp}=0$):

$$J\dot{\omega} = \frac{P_G + P_{imp} - P_{el}}{\omega}$$

- Total generation (synchronous+wind) remains constant.
- Inertia J reduced.
- **Consequence: Frequency drops faster -> increased load shedding**
- Possibly voltage problems because of reduced reactive power reserve in the „island“.
- **Power reduction of wind generators following to low voltages can make the situation worse.**

DigSILENT Seminar: Grid Integration of Wind Energy – 24./25.03.2009 – Cape Town/South Africa

Wind Generator Impact on System Stability - Conclusions

Wind generation has:

- **Positive** influence on transient stability constrained **export** limits.
- **Negative** impact on voltage stability constrained **import** limits if:
 - Reactive reserves are lowered -> additional SVCs, SynCons required.
 - Unreliable power output -> „low voltage ride-through capability“ required
- **Negative** impact on **frequency drops** in case of islanding during power import.
